Exercise 4

Write the JavaScript code to check if user input is a number, and if so, to determine whether it is an integer or a real number, and to display a message corresponding to each case.

Note: User input is always treated as a string. JavaScript performs implicit conversions based on the context of data use. However, it is recommended to always use explicit conversions.

`Number(string):` converts a string of digits into a number; it returns `NaN` (Not a Number) if the string contains characters other than digits.

`isNaN(value):` checks if the value is a number; it returns `true` if it is not.

`parseInt(value):` converts the value (number or string) into an integer.

`parseInt("123aw")` returns the integer 123.

`parseInt("b45")` returns NaN.

`parseInt(12.56)` returns the integer 12.

`parseFloat(value)`: same logic as `parseFloat`, it returns a real number if possible, or NaN.

Exercise 5

Write the JavaScript code that allows the user to enter an integer, count, and display the number of even integers between 1 and the entered number.

A number is even if the remainder of its division by 2 is 0.

To find the remainder, we use the percent operator (%). For example: 5 % 2 returns 1.

Exercise 6

Write JavaScript code that allows the user to enter multiple values, one at a time, ignores non-numeric values, sums the entered numbers, stops if the sum exceeds 100, and displays the result.
